

BioPharma Innovations - Phase III CardioShield Clinical Trial

Trial Registry: NCT-08472910 | Principal Investigator: Dr. Elena Vance | Completed: August 2024

1. EXECUTIVE SUMMARY & STUDY DESIGN

CardioShield (CS-402) is a novel oral selective receptor antagonist evaluated in a randomized, double-blind, placebo-controlled trial across 12 academic medical centers. A total of 620 adult participants aged 45-75 with diagnosed Stage 2 hypertension were randomized 1:1 to receive CardioShield 20mg once daily or matching placebo for 24 consecutive weeks.

2. PRIMARY EFFICACY ENDPOINTS

The primary endpoint was the mean reduction in systolic blood pressure (SBP) from baseline at Week 12. Patients in the CardioShield cohort demonstrated a statistically significant mean SBP reduction of 14.8 mmHg ($p < 0.001$) compared to 4.2 mmHg in the placebo arm. Diastolic blood pressure (DBP) showed a corresponding reduction of 9.1 mmHg ($p < 0.01$) at Week 12.

3. SAFETY & ADVERSE EVENTS PROFILE

Overall incidence of treatment-emergent adverse events was 11.4% in the active arm versus 9.8% in the placebo group. Reported events included mild transient dizziness (4.2%), low-grade headache (3.1%), and peripheral edema (1.8%). No drug-related serious adverse events or deaths occurred during the 24-week evaluation period.

4. REGULATORY STATUS & MISSING INDICATIONS

CardioShield is submitted for FDA Fast Track consideration for adult hypertension management. Note: Pediatric dosage guidelines and long-term 5-year renal outcomes were not part of this study protocol and remain unstudied.
